

# Simple Task

You are given a simple Java program that validates login information, mainly password. The program has one class that includes a method to validate password based on length. A test case exists but it fails.

Using Test-Driven development, you are asked to fix the test cast, and have the password validates. A password is valid If it has more than 6 characters and fewer than 12. You may add other constraints, If time limits.

Similarly, a username contain letter “x” at start of username. For example “xUserName”.
